

CS 33

Linkers

gcc Steps

1) Compile

- to start here, supply .c file
- to stop here: `gcc -S` (produces .s file)
- if not stopping here, gcc compiles directly into a .o file, bypassing the assembler

2) Assemble

- to start here, supply .s file
- to stop here: `gcc -c` (produces .o file)

3) Link

- to start here, supply .o file

The Linker

- **An executable program is one that is ready to be loaded into memory**
- **The linker (known as ld: /usr/bin/ld) creates such executables from:**
 - **object files produced by the compiler/assembler**
 - **collections of object files (known as libraries or archives)**
 - **and more we'll get to soon ...**

Linker's Job

- **Piece together components of program**
 - **arrange within address space**
 - » **code (and read-only data) goes into text region**
 - » **initialized data goes into data region**
 - » **uninitialized data goes into bss region**
- **Modify address references, as necessary**

A Program

```
int nprimes = 100;
```

data

```
int *prime, *prime2;
```

bss

```
int main() {
```

```
    int i, j, current = 1;
```

```
    prime = (int *)malloc(nprimes*sizeof(*prime));
```

```
    prime2 = (int *)malloc(nprimes*sizeof(*prime2));
```

dynamic

```
    prime[0] = 2; prime2[0] = 2*2;
```

```
    for (i=1; i<nprimes; i++) {
```

```
        NewCandidate:
```

```
        current += 2;
```

```
        for (j=0; prime2[j] <= current; j++) {
```

```
            if (current % prime[j] == 0)
```

```
                goto NewCandidate;
```

```
        }
```

```
        prime[i] = current; prime2[i] = current*current;
```

```
    }
```

```
    return 0;
```

```
}
```

text

... with Output

```
int nprimes = 100;
int *prime, *prime2;
int main() {
    ...
    printcol(5);
    return 0;
}
```

```
void printcol(int ncols) {
    int i, j;
    int nrows = (nprimes+ncols-1)/ncols;
    for (i = 0; i<nrows; i++) {
        for (j=0; (j<ncols) && (i+nrows*j < nvals); j++) {
            printf("%6d", prime[i + nrows*j]);
        }
        printf("\n");
    }
}
```

... Compiled Separately

should refer to same thing

```
int nprimes = 100;
int *prime, *prime2;
int main() {
    ...
    printcol(5);
    return 0;
}
```

primes.c

ditto

```
extern int nprimes;
int *prime;
void printcol(int ncols) {
    int i, j;
    int nrows = (nprimes+ncols-1)/ncols;
    for (i = 0; i<nrows; i++) {
        for (j=0; (j<ncols)
            && (i+nrows*j < nvals); j++) {
            printf("%6d", prime[i + nrows*j]);
        }
        printf("\n");
    }
}
```

printcol.c

gcc -c primes.c

gcc -c printcol.c

gcc -o primes primes.o printcol.o

Global Variables

- **Initialized vs. uninitialized**
 - initialized allocated in *data* section
 - uninitialized allocated in *bss* section
 - » implicitly initialized to zero
- **File scope vs. program scope**
 - *static* global variables known only within file that declares them
 - » two of same name in different files are different
 - » e.g., `static int X;`
 - non-static global variables potentially shared across all files
 - » two of same name in different files are same
 - » e.g., `int X;`

Scope

Static Local Variables

```
int *sub1() {  
    int var = 1;  
    ...  
    return &var;  
    /* amazingly illegal */  
}
```

```
int *sub2() {  
    static int var = 1;  
    ...  
    return &var;  
    /* (amazingly) legal */  
}
```

Reconciling Program Scope (1)

tentative definition

```
int X;  
  
void func1( ...) {  
    ...  
}
```

file1.c

(complete) definition

```
int X=1;  
  
void func2( ...) {  
    ...  
}
```

file2.c

Where does X go?

What's its initial value?

- tentative definitions overridden by compatible (complete) definitions
- if not overridden, then initial value is zero

Reconciling Program Scope (2)

```
int X=2;  
  
void func1( ...) {  
    ...  
}
```

file1.c

```
int X=1;  
  
void func2( ...) {  
    ...  
}
```

file2.c

What happens here?

Reconciling Program Scope (3)

```
int X=1;

void func1( ...) {
    ...
}
```

file1.c

```
int X=1;

void func2( ...) {
    ...
}
```

file2.c

Is this ok?

Reconciling Program Scope (4)

```
extern int X;  
  
void func1( ...) {  
    ...  
}
```

file1.c

```
int X=1;  
  
void func2( ...) {  
    ...  
}
```

file2.c

What's the purpose of “extern”?

Default Values (1)

```
float seed = 1.0;
```

```
int PrimaryFunc(float arg) {  
    ...  
    SecondaryFunc(arg + seed);  
    ...  
}
```

```
void SecondaryFunc(float arg) {  
    ...  
}
```

Default Values (2)

```
float seed = 2.0; /* want a different seed */
```

```
int main() {  
    ...  
    PrimaryFunc(floatingValue);  
    ...  
}
```

```
void SecondaryFunc(float arg) {  
    /* would like to override default version */  
    ...  
}
```

Default Values (3)

```
__attribute__((weak)) float seed = 1.0;
```

```
int PrimaryFunc(float arg) {  
    ...  
    SecondaryFunc(arg + seed);  
    ...  
}
```

```
void __attribute__((weak)) SecondaryFunc(float arg) {  
    ...  
}
```

Does Location Matter?

```
int main(int argc, char *[]) {  
    return(argc);  
}
```

main:

```
pushq %rbp    ; push frame pointer  
movq  %rsp, %rbp    ; set frame pointer to point to new frame  
movl  %edi, %eax    ; put argc into return register (eax)  
movq  %rbp, %rsp    ; restore stack pointer  
popq  %rbp    ; pop stack into frame pointer  
ret         ; return: pops end of stack into rip
```

Location Matters ...

```
int X=6;  
int *aX = &X;
```

```
int main() {  
    void subr(int);  
    int y=*aX;  
    subr(y);  
    return(0);  
}
```

```
void subr(int i) {  
    printf("i = %d\n", i);  
}
```

Coping

- **Relocation**

- modify internal references according to where module is loaded in memory
- modules needing relocation are said to be *relocatable*
 - » which means they *require* relocation
- the compiler/assembler provides instructions to the linker on how to do this

A Revised Version of Our Program

```
extern int X;
int *aX = &X;
int Y = 1;

int main() {
    void subr(int);
    int y = *aX+Y;
    subr(y);
    return(0);
}
```

main.c

```
#include <stdio.h>
int X;

void subr(int XX) {
    printf("XX = %d\n", XX);
    printf("X = %d\n", X);
}
```

subr.c

```
gcc -o prog -O1 main.c subr.c
```

main.s (1)

```
        .file      "main.c"

47: .LFE11:
47:     .size    subr, .-subr
```

subr should be made
known to others

must be replaced with
.LC0's address

must be replaced with
.LC1's address

must be replaced with printf's
address, expressed as an offset
from the next instruction

subr.s (3)

```
0:      .comm    X, 4, 4
0:      .ident   "GCC: (Debian 4.7.2-5) 4.7.2"
0:      .section .note.GNU-stack,"",@progbits
```

**reserve 4 bytes of 4-byte aligned
storage for X**

Quiz 1

```
int X;  
int func(int arg) {  
    static int Y;  
    int Z;  
  
    ...  
}
```

Which of *X*, *Y*, *Z*, and *arg* would the compiler know the addresses of at compile time?

- a) all
- b) just *X* and *Y*
- c) just *arg* and *Z*
- d) none

ELF

- **Executable and linking format**
 - **used on most Unix systems**
 - » pretty much all but Mac OS
 - **defines format for:**
 - » **.o (object) files**
 - » **.so (shared object) files**
 - » **executable files**

Doing Relocation

- **Linker is provided instructions for updating object files**
 - **lots of ways addresses can appear in machine code**
 - **three in common use on x86-64**
 - » **32-bit absolute addresses**
 - **used for text references**
 - » **64-bit absolute addresses**
 - **used for data references**
 - » **32-bit PC-relative addresses**
 - **offset from current value of rip**
 - **used for text and data references**

main.o (1)

ELF Header:

```
Magic:    7f 45 4c 46 02 01 01 00 00 00 00 00 00 00 00 00
Class:                                ELF64
Data:                                2's complement, little endian
Version:                               1 (current)
OS/ABI:                                UNIX - System V
ABI Version:                           0
Type:                                  REL (Relocatable file)
Machine:                               Advanced Micro Devices X86-64
Version:                               0x1
Entry point address:                   0x0
Start of program headers:               0 (bytes into file)
Start of section headers:               296 (bytes into file)
Flags:                                 0x0
Size of this header:                    64 (bytes)
Size of program headers:                 0 (bytes)
Number of program headers:               0
Size of section headers:                 64 (bytes)
Number of section headers:               13
Section header string table index: 10
```

main.o (2)

32-bit, PC-relative address

Relocation section '.rela.text' at offset 0x5c0 contains 3 entries:

.rodata.str1.1:
XX = %d\n\0X = %d\n\0

Quiz 2

Consider the following 5-byte instruction:

ea 00 00 00 00

ea is the opcode for the call instruction with a 32-bit PC-relative operand.

**Suppose this instruction is at location 0x1000.
To what location would control be transferred if the instruction were executed as is?**

- a) 0**
- b) 0x1000**
- c) 0x1001**
- d) 0x1005**
